Letters (There are other letters we will see later)

- A symmetric w.r.t. principle axis
- B antisymmetric w.r.t. principle axis

Subscript numbers are based on symmetry w.r.t. rotation about a C_2 perpendicular to the principal axis.
 In the absence of a C_2 a vertical mirror plane perpendicular to the plane of the molecule is used instead
 subscript 1 symmetric w.r.t. a C_2 that is perpendicular to the principle axis
 subscript 2 antisymmetric w.r.t. a C_2 that is perpendicular to the principle axis

Subscripted u and g

- subscript g symmetric w.r.t. inversion
- subscript u antisymmetric w.r.t. inversion

Tick Marks

- ' symmetric w.r.t. σ_h
- " antisymmetric w.r.t. σ_h

How do we use Character Tables.

To examine the symmetry of the thing we are interested in (molecular motions, orbitals, symmetry adapted linear combinations of atomic orbitals...) we create a reducible representation of the symmetry operations acting on the thing we are interested in.

We use linear algebra to determine the irreducible representations that must be combined to form the reducible one that we just found.

We use the functions in the character tables to interpret our results.

For each operation and each item add 1, 0 or -1 to the value for χ based on whether there is no change (1), the items changes position (0), or doesn't change position but changes sign (-1).
